

Crash Recovery Chapter 18

No office hours on W 11/30.

Adding office hours on Th 12/1 from 3pm-5pm.

Move PS#5 due date to 12/5?

Review: The ACID properties

- Atomicity: All actions of a transaction happen, or none happen.
- Consistency: If each Xact is consistent, and the DB starts consistent, it ends up consistent.
- Isolation: Execution of one Xact is isolated from that of other Xacts.
- Durability: If a Xact commits, its effects persist.
- * The Recovery Manager guarantees Atomicity & Durability.

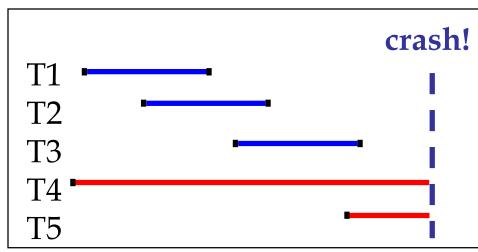

Motivation

- Atomicity:
 - Transactions may abort ("Rollback").
- Durability:
 - What if DBMS Crashes?
 ("Worse case", a few unfinished Xacts are lost)

Desired state after system restarts?

- T1, T2 & T3 should be durable.
- T4 & T5 should be aborted (no effect).

Assumptions

- Concurrency control is in effect.
 - In particular, locks are acquired on blocks before reading or writing and are released after commit.
- Updates are happening "in place".
 - i.e. data is overwritten on (or deleted from) non-volatile disk.
 - "In place" implies, we are not using a temporary/in memory database, but one that is persistent.
- Can you think of a simple scheme to guarantee Atomicity & Durability?

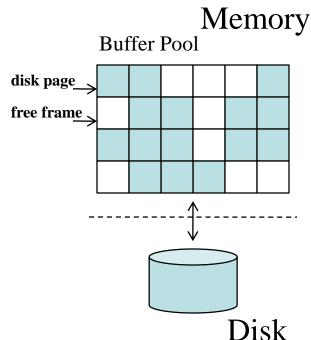

Recalling the Buffer Pool

Which of the following types of pages might be found in the buffer pool?

- A) Pinned interior nodes of a B+-tree
- B) Sorted pages from a recent sort-merge-join
- C) A bucket of <key, rid> pairs from a hash index
- D) A "dirty" updated page from a relation that has yet to be flushed to disk
- E) All of the above

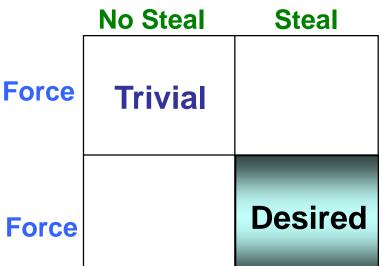

Of these, which must be tracked in by the log?

Handling the Buffer Pool

- Force every write to disk? Stall DBMS until completed
 - Poor response time.
 - But provides durability.
- Steal buffer-pool frames from uncommitted Xacts? (flush dirty frames, only No Force when a new frame is needed)
 - If not, poor throughput (multiple writes to same page).
 - If so, how can we ensure atomicity?

More on Steal and Force

- STEAL (why enforcing Atomicity is hard)
 - What if a page, P, dirtied by some unfinished Xact is written to disk to free up a buffer slot, and the Xact later aborts?
 - Must remember the old value of P at steal time (to *UNDO* the page write).
- * **NO FORCE** (why enforcing Durability is hard)
 - What if system crashes before a page dirtied by a committed Xact is flushed to disk?
 - Write as little as possible, in a convenient place, at commit time, to support *REDO*ing modifications.

Basic Idea: Logging

- * Record sufficient information to REDO and UNDO every change in a *log*.
 - Write and Commit sequences saved to log (on a separate disk or replicated on multiple disks).
 - Minimal info (diff) written to log, so multiple updates fit in a single log page.
- Log: An ordered list of REDO/UNDO actions
 - Log record contains:
 <XID, pageID, offset, length, old data, new data>
 - and additional control info (which we'll see soon).

Write-Ahead Logging (WAL)

- The Write-Ahead Logging Protocol:
 - 1. Modification of a database object must *first* be recorded in the log, and the log updated, *before* any change to the object
 - 2. Must write all log records of a Xact <u>before it</u> <u>commits</u>.
- * #1 guarantees Atomicity.
- * #2 guarantees Durability.
- Exactly how is logging (and recovery!) done?
 - We'll study the ARIES algorithm.

- Each log record has a unique Log Sequence Number (LSN).
 - LSNs are always increasing.
- * Each <u>data page</u> contains a pageLSN.
 - LSN of most recent page modification.
- System keeps track of flushedLSN.
 - Max LSN flushed from the page buffer so far.
- ❖ WAL: Before a page is written,
 - pageLSN ≤ flushedLSN

Log pages on disk

"Log tail"

in RAM

pageLSN

Log Records

LogRecord fields:

prevLSN
XID
type
pageID
length
offset
only
before-image
after-image

Possible log record types:

- Update
- * Commit
- * Abort
- End (signifies end of commit or abort)
- Compensation Log Records (CLRs)
 - for UNDO actions

Other Log-Related State

Transaction Table:

- One entry per active Xact.
- Contains XID, status (running/committed/aborted), and lastLSN due to Xact

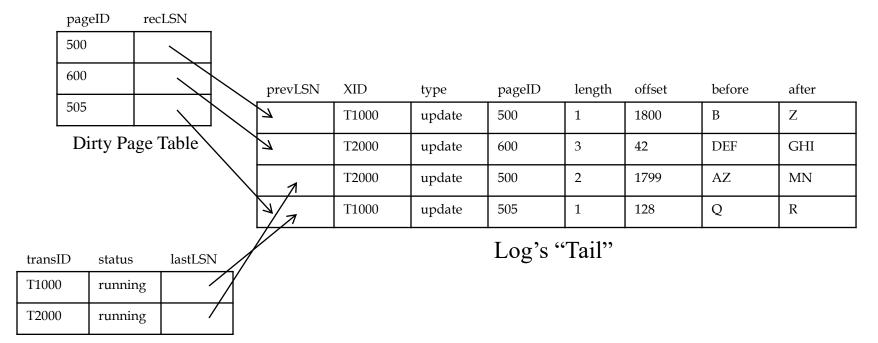

* Dirty Page Table:

- One entry per dirty page in buffer pool
- Contains recLSN -- the LSN of the log record which first dirtied the page

Log and Table Entries

Transaction Table

Normal Execution of an Xact

- Series of reads & writes, terminated by commit or abort.
 - We will assume that write is atomic on disk.
 - In practice, additional details to deal with non-atomic writes.
- * Strict 2PL.
- * STEAL, NO-FORCE buffer management, with Write-Ahead Logging.

Checkpointing

- Periodically, the DBMS creates a <u>checkpoint</u>, to minimize recovery time in the event of a system crash. What is written to log and disk:
 - begin_checkpoint record: Indicates when chkpt began.
 - end_checkpoint record: Contains current *Xact table* and *dirty page table*. This is a "fuzzy checkpoint":
 - Xacts continue to run; so these tables are accurate only as of the time of the begin_checkpoint record.
 - No attempt to force dirty pages to disk; effectiveness of checkpoint limited by oldest unwritten change to a dirty page. (So it's a good idea to periodically flush dirty pages to disk!)
 - Store LSN of chkpt record in a safe place (master record).

The Big Picture: What's Stored Where

LogRecords

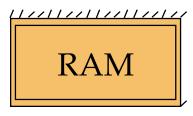

prevLSN
XID
type
pageID
length
offset
before-image
after-image

Data pages

each with a pageLSN

master record

Xact Table

lastLSN status

Dirty Page Table recLSN

flushedLSN

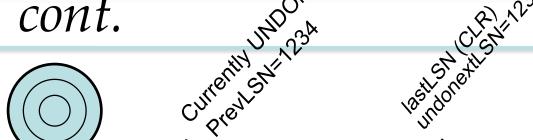

Simple Transaction Abort

- For now, consider an explicit abort of a Xact.
 - No crash involved.
- We want to "play back" the log in reverse order, UNDOing updates.
 - Get lastLSN of Xact from Xact table.
 - Can follow chain of log records backward via the prevLSN field.
 - Before starting UNDO, write an Abort log record.
 - For recovering from crash during UNDO!

Abort, cont.

- * To perform UNDO, must have a lock on data!
- * Before restoring old value of a page, write a Compensation Log Record (CLR):
 - Continue logging while you UNDO!!
 - CLR has one extra field: undonextLSN
 - Points to the next LSN to undo (prevLSN of log entry)
 - CLRs are never Undone (but they might be Redone when repeating history: guarantees Atomicity!)
- ❖ At end of UNDO, write an "end" log record.

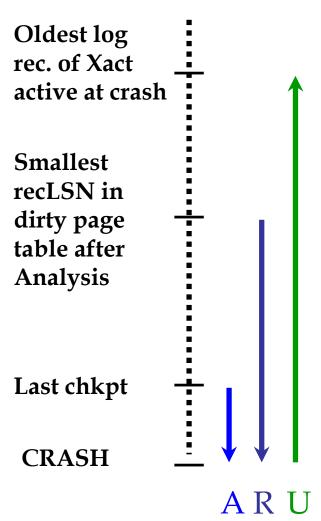

Transaction Commit

- Write commit record to log.
- All log records up to Xact's lastLSN are flushed on a commit.
 - Guarantees that flushedLSN ≥ lastLSN.
 - Note that log flushes are sequential, synchronous writes to disk.
 - Many log records per log page.
- Commit() returns.
- Write end record to log.

Crash Recovery: Big Picture

- □ Start from a checkpoint (found via master record).
- □ ARIES 3 phases. Need to:
 - Analysis: Figure out which Xacts committed since last checkpoint, and which did not finish.
 - REDO all logged actions.
 Repeats "writing" history to recreate buffer pool
 - UNDO effects of unfinished "loser" Xacts.

Recovery: The Analysis Phase

- Reconstruct state at checkpoint.
 - via the end_checkpoint record.
- Scan log forward from checkpoint.
 - Look for End records: Remove Xact from Xact table because it safely completed.
 - Other records: Add Xact to Xact table, set lastLSN=LSN, change Xact status on commit.
 - Update record: If P not in Dirty Page Table,
 - Add P to D.P.T., set its recLSN=LSN.

Recovery: The REDO Phase

- We repeat History to reconstruct state at crash:
 - Reapply all updates (even of aborted Xacts!), redo CLRs.
- ❖ Scan forward from log record of the smallest recLSN in the dirty page table. For each CLR or update log rec LSN, REDO the action unless:
 - Affected page is not in the Dirty Page Table, or
 - Affected page is in D.P.T., but has recLSN > LSN, or
 - pageLSN (in DB) \geq LSN.
- * To REDO an action:
 - Reapply logged changes (restore to before state).
 - Set pageLSN to LSN. No additional logging!

Recovery: The UNDO Phase

ToUndo={ l | l a lastLSN of a "loser" Xact}

Repeat:

- Choose largest LSN among ToUndo.
- If this LSN is a CLR and undonextLSN==NULL
 - Write an End record for this Xact.
- If this LSN is a CLR, and undonextLSN != NULL
 - Add undonextLSN to ToUndo
- Else this LSN is an update. UNDO the update, write a CLR, add prevLSN to ToUndo.

Until ToUndo is empty.

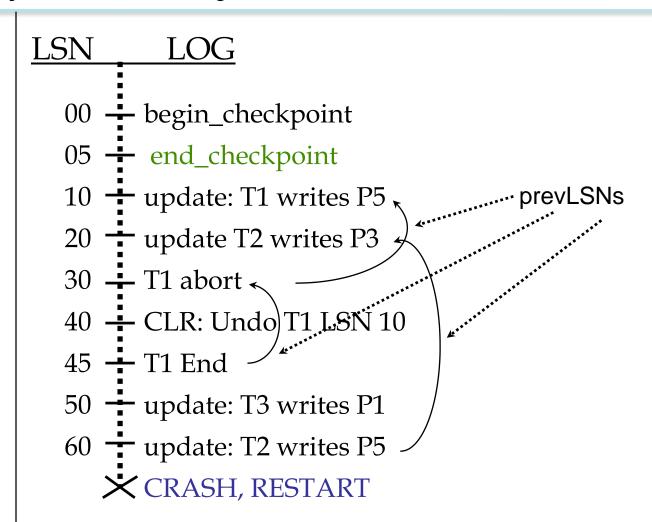

Example of Recovery

Xact Table
lastLSN
status
Dirty Page Table
recLSN
flushedLSN

ToUndo

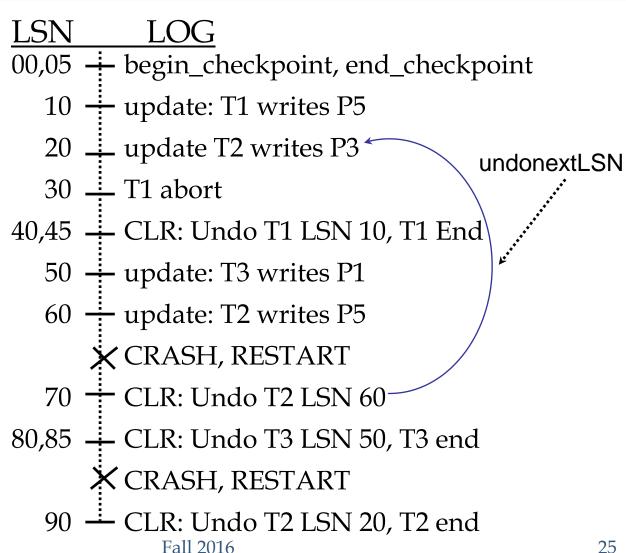

Example: Crash During Restart!

RAM

Xact Table lastLSN status **Dirty Page Table** recLSN flushedLSN

ToUndo

Additional Crash Issues

- What happens if system crashes during Analysis? During REDO?
- * How to limit the amount of work in REDO?
 - Flush dirty pages asynchronously in the background.
 - Watch out for "hot spots"!
- * How to limit the amount of work in UNDO?
 - Avoid long-running Xacts.

Summary of Logging/Recovery

- Recovery Manager guarantees Atomicity & Durability.
- Uses WAL to allow STEAL/NO-FORCE w/o sacrificing correctness.
- LSNs identify log records; linked into backwards chains per transaction (via prevLSN).
- pageLSN allows comparison of data page and log records.

Summary, Cont.

- Checkpointing: A quick way to limit the amount of log to scan on recovery.
- Recovery works in 3 phases:
 - Analysis: Forward from checkpoint.
 - Redo: Forward from oldest recLSN.
 - Undo: Backward from end to first LSN of oldest Xact alive at crash.
- Upon Undo, write CLRs.
- Redo "repeats history": Simplifies the logic!
